Abstract.

BACKGROUND: Workers are exposed to occupational health hazards from physical, chemical, biological, ergonomic, and psychological agents. Assessing occupational health risks is vital for executing control measures to protect employees' health against harmful occupational agents.

OBJECTIVE: The present study aimed to identify, evaluate, and prioritize occupational health risks to assist senior management in determining where to allocate the budget to carry out the required corrective actions in the oilfields project.

METHODS: This descriptive-analytical cross-sectional study was performed in 2021 among Iran's Sarvak Azar oil field job groups. The occupational health risk was assessed using the Harmful Agents Risk Priority Index (HARPI) as a semi-quantitative method. Then, to simplify decision-making and budget allocation, we reported HARPI final score in the Pareto principle format.

RESULTS: The results show that in this oil field, controlling exposure to adverse lighting, improving the thermal conditions and ergonomics, and preventing noise exposure has the highest priority, with scores of 6342, 5269, 5629, and 5050, respectively. Production, HSE, laboratory, and commissioning need the most health care measures with scores of 8683, 5815, 5394, and 4060, respectively.

CONCLUSION: HARPI could be used to prioritize occupational health hazards, and this method can simplify managers' decisions to allocate resources to implement control measures.

Keywords: Workplace, health priorities, decision making, health planning

1. Introduction

Workplace injuries and conditions were the direct cause of about 2.5 million deaths worldwide in 2014 [1]. Approximately 85 % of these were due to work-related diseases, and 15% resulted from accidents [2]. On the other hand, studies show that risk assessment is focused on workplace safety [3–5]. In addition, studies show that the lack of an integrated risk management plan covering all aspects of occupational health and safety (OHS) can increase work-related accidents and diseases [6]. Regardless, in addition to workplace safety conditions, workers are exposed to occupational health hazards from physical, chemical, biological, ergonomic, and psychological agents [7–10]. Risk management is the main subject of the preventive strategy for occupational safety and health (OSH), and it has become a lawful commitment for employers in many countries [11]. According to the European Agency for Safety and Health statement, risk assessment is the basis of OHS risk management [12]. One of the significant factors influencing health and safety management is the improvement of risk assessment techniques to assure the achievement of health and safety programs [11]. In occupational environments, each identified harmful agent is assessed individually by comparing exposure levels to occupational exposure limits (OELs) or other health-based guidelines. It is not common to evaluate the combined risk from simultaneous exposure to multiple stressors in occupational (and non-occupational) environments [10]. According to the history of attention to safety issues and the spread of harmful health factors in work environments, many industrialized countries and international organizations responsible for maintaining safety and health have recently sought to develop different risk assessment methods [13]. But choosing a suitable method depends on the conditions and experience of those who use them, and each method has its strengths and weaknesses [14]. Therefore, to evaluate the conditions more accurately, the researchers suggest that quantitative and qualitative methods be used in a consolidated manner [13, 14]. The oil industry and its derivatives have a specific place in oil-producing countries. This industry's high number of workers necessitates further studies in occupational health engineering services [15, 16]. On the other hand, we should note that one of the main tasks of risk assessment as a management tool is simplifying the perception of subjects and decisions. Therefore, the risk management process should focus on selecting remedial actions with the desired

impact, the assumed benefits at an acceptable cost, and resource savings [17]. In general, assessing occupational health risks to protect employees' health against harmful occupational factors is a necessity that requires more attention than before in terms of the development of risk management methods. Therefore, we conducted this study intending to: manage occupational health risks; identify, evaluate, and prioritize employees' exposure to harmful factors in the workplace; and in order to help the senior management in determining where to spend the allocated budget, to carry out the necessary corrective measures in the Sarvak Azar oil field in 2021. This field is active in western Iran, with an operational capacity of producing 65000 barrels per day. The reservoir of this field is shared with the Badra oil field in Iraq and is located along the Chengoleh oil field. The number of employees in this industry is 840, with an average age of 32.02 ± 6.07 years.

2. Material and methods

The risk management process in this study includes four steps as follows;

2.1. Workplace harmful agent's identification

At this step, we formed a team of experts familiar with Health, Safety, And Environment (HSE) and the workplace. Based on the checklists and guidelines provided by the Iranian Environment and Occupational Health Centre (IEOHC), we classified a list of the most common harmful factors in the workplace. In addition, the human resource information related to each job group, such as the number of people, was specified [18, 19].

2.2. Harmful agent's measurement

In the second step, we used the Ministry of Health and Medical Education (MHME)-approved instructions (OELs) to measure the harmful occupational health agents for the different job groups.

2.2.1. Harmful Physical Agents (HPA) and analysis posture (AP)

We analyze the intensity of noise, types of rays, lighting, heat stress intensity, and ergonomics condition (analysis posture) according to the MHME standard methods, including OEL – NV – 9505, OEL – R – 9506, OEL – L – 9507, OEL-HC-9508,

and OEL – E – 9509 respectively. In addition, we applied following devices to measuring agents. TES 1350 C (Noise), EXTECH radiometer 480846 (magnetic fields), Hagner EC1X (Ultraviolet), Hagner EC1 (Infrared), EXTEC HT30 (Heat stress), RULA, REBA, ROSA, and QEC Worksheets and software.

2.2.2. Harmful Chemical Agents (HCA)

The National Institute of Occupational Safety and Health (NIOSH) and Occupational Safety and Health Administration (OSHA) standard methods also use the following devices to measure the pollutants in a worker's breathing zone.

- Volatile organic compounds (VOCs): NIOSH 2549 – 1501, [SKC AirLite pump, Flow rate: 0.2 (lit/min) - Adsorbent: activated carbon 50/100 mg].

- Dust: NIOSH 0500-NIOSH 0600, [SKC model Air Check touch pump, Flow rate: 1.75 - 2.5 (lit/min) and PVC filter].
- Acid: NIOSH 7909, OSHA ID113, [SKC Air Check touch pump, Flow: 2 (lit/min), Quartz fiber filter, Mixed Cellulose Membrane Filter (MCEF)].

2.3. Risks prioritization

We used Tables 1 and 2 to prioritize the risk caused by exposure to the measured pollutants; the intensity and effects of the measured factors were equated with Exposure Rate (ER) and Hazard Rate (HR) values. Using these tables helps to eliminate mathematical dimensions such as lux, decibels, etc. Then, we applied equation 1 to calculate the weight factor (WF_i) of each agent [20].

Table 1
Standard limits of occupational exposure to HPA, AP and HCA (ER)

Harmful agents	Exposure rate				
	1	2	3	4	5
Noise	–	–	$E \leq AL$	$AL < E \leq OEL$	$E > OEL$
Lighting	$E \geq OEL$	–	–	–	$E < OEL$
Rays	$E \leq 25\%OEL$	$25\%OEL < E \leq 50\%OEL$	$50\%OEL < E \leq 75\%OEL$	$75\%OEL < E \leq 100\%OEL$	$E > 100\% OEL$
Heat stress	–	–	$E \leq AL$	$AL < E \leq 100\%OEL$	$E > 100\% OEL$
QEC Score	–	$S \leq 40\%$	$41\% \leq S \leq 50\%$	$51\% \leq S \leq 75\%$	$S > 75\%$
RULA and REBA	–	Level 1	Level 2	Level 3	Level 4
ROSA Score	–	$S < 5$	$S \geq 5$	–	–
Single chemical contaminant	$E \leq 25\%OEL$	$25\%OEL < E \leq 50\%OEL$	$50\%OEL < E \leq 75\%OEL$	$75\%OEL < E \leq 100\%OEL$	$E > 100\% OEL$
Chemical synergic effects	$E \leq 1$	–	–	–	$E > 1$

Table 2
Consequences of exposure to HPA, AP and HCA (HR)

Hazard Rate Catastrophic (5)	Serious irreversible health or physiological effects, reproductive toxins, life-threatening consequences, lack of light, and multiple deaths due to accident-prone sound levels. The carcinogenic, mutagenic and teratogenic effects of this substance are well known. Elements classified by ACGIH and IARC as Category A1 and Group 1.
Severe (4)	One death, irreversible or debilitating injury to 1 or more persons, chronic progressive complications such as hearing loss, pneumococcal, obstructive pulmonary disease. Chronic progressive complications such as hearing loss, pneumococcosis, and obstructive pulmonary disease. ACCIH Class A2 substance. IRAC class group A2, highly corrosive substances ($0 < PH < 2$ or $11.5 < PH < 14$).
Moderate (3)	Reversible health effects of downtime (musculoskeletal disorders, vibration effects, manual load carrying, physical effects of sunburn, heat stress, neurological effects other than anaesthesia, non-fatal No airborne infections, ultraviolet, infrared, electromagnetic field complications). Substances that ACGIH has placed in class A3. Group B2 materials in IRAC classification. Corrosive substances ($5 < PH < 3$ or $12 < PH < 9$) and respiratory sensitizers.
Minor (2)	Reversible health effects, treatment with no downtime, bacterial food poisoning, sunburn, anaesthesia required. A substance that has reversible effects on the skin, eyes, and mucous membranes, but the effects are not strong enough to cause serious harm to humans. A substance classified as a class A4 carcinogen by the ACGIH. Substances with skin irritants and irritants.
Negligible (1)	No effect on performance, reversible effects, first aid required mild muscle discomfort and headache. A substance classified as a class A5 carcinogen by ACGIH.

$$WF_i = \sqrt{ER \times HR} \quad (1)$$

Then we used equation 2 to calculate Harmful Agents Risk Priority Index (HARPI) (16).

$$HARPI = \frac{\sum_{i=1}^n WF_i \pi_i t_i}{\sum PT} \times 100 \quad (2)$$

153 π_i : Number of people exposed to pollutants

154 t_i : Average exposure time (hours)

155 P: Total number of people

156 T: Total exposure times

157 2.4. Evolution and decision-making

158 In the last step, we analyze and compare the HARPI
 159 Scores in the Pareto principle format to better under-
 160 stand and simplify the decision-making and budget
 161 allocation of the results obtained through the present
 162 study. The Pareto principle is a simple technique with
 163 the logic of cumulative frequency for data analysis.
 164 Pareto's 80/20 principle says that approximately 80%
 165 of the consequences come from 20% of the cause
 166 (80 : 20 Rule) [21]. Therefore, according to the Pareto
 167 principle, after obtaining the maximum and minimum
 168 HARPI values, the range of discounts obtained is
 169 divided into three parts. Harmful agents in the range
 170 of 20% of the upper boundary of the domain have
 171 the highest management priority, and harmful agents
 172 in the range of 20% of the lower limit of the spec-
 173 trum have the lowest priority, whereas the rest were
 174 cases between 20 to 80% of the domain evaluated
 175 with moderate priority (Table 3). Finally, according
 176 to the results, the budget is allocated based on the
 177 organization's acceptable risk level.

178 3. Results

179 We identified 14 job groups in the studied industry
 180 in the first stage by exploring the human resources
 181 database. Then according to the nature of the tasks,
 182 the employees were divided into operational and
 183 administrative groups. Table 4 and Figs. 1 and 2
 184 show the results related to investigating the HARPI
 185 for administrative employees and the harmful fac-
 186 tors identified. For operational employees, the results

187 are given in Table 5 and Figs. 3 and 4. In the tables
 188 and figures, the number zero indicates that the harm-
 189 ful factor has not been identified for the investigated
 190 occupational groups. Also, in some job groups, all
 191 employees are in the administrative department, so
 192 results in corresponding figures and tables of the oper-
 193 ational section, the related values reported equal to
 194 zero.

195 In the next step, by summing the HARPI values
 196 calculated for the administrative and operational divi-
 197 sions, the general conditions of prioritizing harmful
 198 agents has been scrutinized, and the priority of job
 199 groups in terms of corrective and management mea-
 200 sures has been shown within the scope of the study.
 201 The results are shown in Figs. 5 and 6, respectively.
 202 According to Table 3, the results obtained from the
 203 present study are calculated and shown in Table 6
 204 based on Pareto's principle.

205 4. Discussion

206 Risks and the concept of risk and risk-taking
 207 are increasingly preoccupying people, nations, com-
 208 munities, and scientists. Many fields nowadays are
 209 fixated on assessing, handling, or foreseeing a broad
 210 kind of risks from industry and manufacturing to
 211 health and society care and education [22, 23]. In
 212 2018, Tian et al. conducted a study investigating
 213 the methodology of different occupational health
 214 risk assessment (OHRA) models to understand the
 215 qualitative and quantitative differences between the
 216 standard OHRA models in industries. This study uses
 217 common health risk assessment models, including;
 218 the Environmental Protection Agency (EPA), Aus-
 219 tralia, Romania, Singapore, International Council on
 220 Mines and Metals, and Control of Substances Haz-
 221 arduous to Health (COSHH) models were compared
 222 quantitatively and qualitatively. Qualitative compar-
 223 isons showed that each OHRA model has strengths
 224 and limitations and offers a diverse distribution at
 225 different levels for each evaluation index. The Singa-
 226 pore, COSHH, and EPA models had a much higher
 227 comprehensive advantage than the others for all indi-
 228 cators. Quantitative comparisons showed that the
 229 three models also have a more vital ability to detect

Table 3
HARPI results classification analyzing in Pareto principle

Risk rate	High priority	Medium priority	Low priority
HARPI score in Pareto principle format	The most leading 20% of the HARPI	Middle range of the HARPI	The lowest leading 20% of the HARPI

Fig. 1. Calculated HARPI score for harmful agents in administrative section.

Fig. 2. Calculated HARPI score for job groups in administrative section.

230 differences in risk ratios between different industries.
 231 The Singapore models had the strongest correlation
 232 with other models. In general, the results of this
 233 study showed that each model had its strengths and
 234 limitations depending on its unique methodological
 235 principles. A combination of the EPA, Singapore, and
 236 COSHH models may be helpful in the development
 237 of the OHRA strategy [14]. In addition, Niemeier
 238 et al. explored practical cumulative risk assessment
 239 methodologies and tools to meet the demands of com-
 240 plex and changing work environments. It has been
 241 found to be essential [24]. Therefore, we aimed in this
 242 study to identify, evaluate, and prioritize occupational
 243 health risks and ultimately assist senior management
 244 in deciding to use the budget to implement the reme-
 245 dial measures required at the Sarvak Azar oil field
 246 by using NCPI and COHRA Models [16, 20]. The
 247 results of the present study, according to Table 4 and
 248 Fig. 1, show that, among the harmful factors iden-

249 tified for office workers, improper posture has the
 250 highest exposure (HARPI Score:2381), and chemical
 251 compounds (TEX) have the lowest amount (HARPI
 252 Score:12). According to Table 4 and Fig. 2, we cal-
 253 culated the highest and lowest HARPI values for
 254 human resources employees (HARPI Score: 1015)
 255 and security (HARPI Score: 45) units. That shows
 256 among the administrative job groups, these units have
 257 the highest and lowest possible vulnerability in expo-
 258 sure to harmful factors. Table 5 and Fig. 3 show that
 259 improper lighting is the harmful factor with the high-
 260 est (HARPI Score: 5513) priority, and TEX has the
 261 lowest (HARPI Score: 982) risk for operational staff.
 262 Figure 4 also shows that among the investigated job
 263 groups, production and process engineering groups
 264 have the highest (HARPI Score: 8616) and lowest
 265 (HARPI Score: 1965) risk of exposure to harmful
 266 factors in the workplace. Figures 5 and 6 show the
 total HARPI values for the harmful agents and job

Table 6
HARPI scores classification in pareto principle

Risk rate	High priority	Medium priority	Low priority
Calculations	$[\text{HARPI}_{\text{Max}} - (\text{HARPI}_{\text{Max}} \times 20\%)]$	$[\text{HARPI}_{\text{Max}} - (\text{HARPI}_{\text{Max}} \times 20\%)] < \text{Medium priority} \leq [\text{HARPI}_{\text{Max}} \times 20\%]$	$[\text{HARPI}_{\text{Max}} \times 20\%]$
HARPI score in Pareto principle	High ≥ 5074	$5074 < \text{Medium} \leq 1268$	Low < 1268
Harmful agents priority at workplace	1- Lighting 2- Heat stress 3- Analysis posture 4- Noise	1. UV 2. EMFs 3. IR 4. Benzene 5. Dust 6. Hydrochloric acid 7. Synergic effect (BTEX)	1- Sulfuric acid 2- Toluene 3- Ethyl benzene 4- Xylene
HARPI score in Pareto principle	High ≥ 6947	$6947 < \text{Medium} \leq 1737$	Low < 1737
Job groups priority at workplace	1- Production	1- HSE 2- Laboratory 3- Commissioning 4- Maintenance 5- Security 6- Logistic 7- Process engineering	1- Human resource 2- Planning 3- Information technology 4- Management 5- Commercial

267 groups investigated in the study scope. Examining the
 268 results from this point of view determines the overall
 269 risk of the studied industry regarding occupational
 270 health. The results show that unfavorable lighting
 271 with a score of 6342 and TEX with a score of 994
 272 have the highest and lowest risks for employees in
 273 the studied industry (Fig. 5). Among the occupational
 274 groups studied, the production, HSE, and laboratory
 275 groups have the highest risk of exposure to harmful
 276 factors in the work environment, and the commer-
 277 cial unit has the least risk (Fig. 6). In addition, to
 adjust the organization’s risk tolerance level based

278 on the Pareto principle, Table 6 shows that the pro-
 279 duction group is exposed to the highest health risk
 280 due to occupational exposures. Lighting, heat stress,
 281 and ergonomic disorders caused by improper posture
 282 and noise in the workplace are the most critical risks
 283 that require control measures. Various studies show a
 284 significant relationship between ergonomic disorders
 285 caused by awkward posture and undesirable lighting
 286 [25]. Musculoskeletal disorders [26] and unfavorable
 287 lighting are the most common harmful factors in the
 288 workplace [27]. Noise is known as the most common
 289 harmful factor in the workplace [16]. The results of
 290

291 this study are consistent with the statements men-
 292 tioned in specialized studies conducted in the field
 293 of harmful elements. In addition, the high priority of
 294 thermal stress in the studied area can be attributed to
 295 the region's climatic conditions [28]. Compared with
 296 the results of studies based on health risk assessment
 297 in the workplace [13, 14], in addition to the number
 298 of exposed people and the duration of exposure, we
 299 removed the mathematical dimensions related to the
 300 measured values. Pure scores are one of the essential
 301 advantages of the method used in this study, which
 302 provides the ability to compare different parameters.

303 5. Conclusion

304 The HARPI can prioritize the results of measuring
 305 and evaluating the harmful agents of the workplaces.
 306 In addition, this method can simplify managers'
 307 decisions to allocate resources to implement control
 308 measures and finally reduce risk levels to an accept-
 309 able level. This method can assess semi-quantitative
 310 risk in other field of HSE, such as the environment
 311 by developing the ER and HR tables.

312 5.1. Study limitations

313 Among the categories of harmful factors in the
 314 workplace, we investigated the most common ele-
 315 ments of physical, chemical agents, and ergonomics.
 316 At the same time, the other cases require special-
 317 ized methods and have a high cost for sampling and
 318 para-clinical tests.

319 5.2. Recommendations

320 For future studies, we recommended that other
 321 researchers in the HSE field expand the ER and HR
 322 tables based on the epidemiology of occupational dis-
 323 eases and their complications. In addition, the main
 324 parameters measured in environmental issues such
 325 as noise pollution, water, soil, and air pollutants are
 326 numerically reported and compared with the standard
 327 limits. Therefore, the development of the above ER
 328 and HR tables can make this method more efficient
 329 by a risk assessment of environmental aspects.

330 Ethical approval

331 The study was approved by the Research
 332 Ethics Committee of the Faculty of Health and

Neuroscience Research Center, Shahid Beheshti
 University of Medical Sciences, Tehran, Iran
 (IR.SBMU.PHNS.REC.1401.051).

336 Informed consent

337 Informed consent was obtained from all partic-
 338 ipants. Each participant received a code to remain
 339 anonymous.

340 Conflict of interest

341 There are no conflicts of interest.

342 Acknowledgments

343 The authors especially appreciate Mr. Ehsan
 344 Purovali (Project manager), Karim Hormazi and
 345 Afshar Nemati (Site manager), Arash Sepahvand
 346 (HSE headquarters office manager), and Masoud
 347 Davoudi (Site HSE manager). In addition, they thank
 348 the participants of the study.

349 Funding

350 Support was received from OICO Project manage-
 351 ment in the Azar oilfield to provide the necessary
 352 materials and equipment for implementing the study.
